Task 6 – Kavach Release and UAT Plan

Release stages, test cases, go-live gates and incident response

1. Release path and accountable owners

Stage	Work / exit evidence	Owner
1. Defect triage & fix	Reproduce 4 incorrect EMI responses and 2 ~40-second disconnects; identify root cause; fix and document code/config changes.	Arjun (backend), Meera (AI/ML before leave); TPM tracks.
2. Integration & network	Obtain client approval for new telephone-provider IPs; verify allow-list, DNS/routing, credentials and end-to-end call path.	Dev + client network team.
3. Build & code review	Merge reviewed changes; pin dependencies/config; run unit and integration tests; create versioned release candidate.	Arjun + relevant engineering owner.
4. QA / regression	Run test suite, compare spoken EMI against approved source of truth, validate call duration, retry behavior and logs; attach evidence.	Sana; Arjun supports.
5. UAT	Execute client-approved scenarios in UAT; record pass/fail, evidence, defects and retests; obtain written acceptance.	Sana coordinates; client business/technical users execute; TPM manages.
6. Production readiness	Verify production configuration, secrets, network, capacity, monitoring, alerting, backups, rollback/disable switch and support rota.	Dev + Arjun + Sana.
7. Go/no-go & deployment	Review all gates; deploy using approved change window and controlled rollout; smoke test.	TPM coordinates; Group CTO/authorized release owner approves; Dev/Arjun deploy.
8. Hypercare	Monitor call success, EMI accuracy, latency/disconnects, errors, costs and incidents; publish updates.	Sana + Arjun + Dev; TPM communicates.

2. Client UAT test cases

#	Test	Expected result / evidence
1	Known borrower with a verified EMI due date and amount.	Agent identifies the intended borrower and speaks the exact amount/date from the approved source; call trace and source record retained.
2	Boundary/varied EMI values, including decimals and large values.	Spoken amount matches source exactly; no rounding, stale value or cross-customer data.
3	Re-run the four scenarios that previously returned wrong EMI amounts.	All pass against expected values; any mismatch is a release-blocking defect.
4	Call runs beyond 40 seconds with normal conversation pauses.	Call remains connected for the designed conversation; no unexplained ~40-second termination.
5	Borrower does not answer / line is busy / voicemail.	Configured safe outcome, retry policy and call disposition are followed; no repeated uncontrolled calls.
6	Borrower asks to repeat or clarify EMI amount/date.	Agent repeats the same verified value and does not fabricate or change it.
7	Telephone route through client's newly approved IP allow-list.	Calls connect successfully from the production-equivalent path; network team confirms approval.
8	Concurrent calls, error handling and end-to-end audit.	Within agreed capacity; failures are logged with correlation IDs; no cross-customer leakage; dashboard/alerts work.

3. Go-live entry gates and approvals

• All critical/high-severity defects affecting EMI correctness, borrower identity, call completion or data privacy are resolved and retested; no known wrong-EMI path remains.
• Client network team has approved and verified the provider's new IP addresses; production call path works.
• UAT pass evidence and written client sign-off are received against agreed acceptance criteria.
• Production build/configuration is reviewed; secrets are managed securely; monitoring, alerting, logging and support ownership are active.
• Rollback/disablement has been rehearsed; backup/configuration recovery is available; deployment and communication plan is approved.
• AI cost overrun is explained, forecasted and accepted by the authorized budget owner; cost guardrails are configured where possible.

Approval: the Nirmal Finance-designated business/technical approver signs UAT acceptance. The Group CTO or delegated internal release authority gives internal production go/no-go approval. TPM coordinates the decision and records both approvals; TPM does not substitute for client acceptance or release authority.

4. Serious post-go-live incident

Immediately stop or disable affected outbound calls if incorrect EMI values, cross-customer disclosure, widespread call failure or another critical issue occurs. Declare an incident, preserve logs/evidence, notify the client and Group CTO through the agreed escalation path, and activate rollback or feature disablement. Assign an incident lead and technical owner, assess scope and customer impact, communicate updates at an agreed cadence, fix and regression-test in a safe environment, obtain required approvals, then resume gradually with heightened monitoring. Complete a root-cause analysis and preventive actions after recovery.

Scheduling note

Meera is on leave Wednesday–Friday and Arjun is reserved for Kavach go-live preparation Thursday–Friday. Complete AI-dependent investigation with Meera before leave, document handover, and do not assume Arjun can simultaneously deliver the Ledger fix and Kavach release work.
